Wisniewski, J.

Antigenic properties of testicular hyaluronidase. J. Wisniewski and M. Weber (*Folia Biol. Warsz.*, 1954, 2, 31-52). The vaccination of rabbits with hyaluronidase from bull testes is described. Rabbit sera contain specific antibodies, demonstrated by pptn. and complement fixation tests, which also neutralise enzymic activity. It is considered that hyaluronidase from bull testis is a complete antigen. A correlation between the antigenic potency of the hyaluronidase and its mol. structure was found. The problem of the mechanism of the neutralisation of enzymic activity by the specific antibodies *in vitro* and *in vivo* is discussed. It is suggested that by the use of a standard antigen (determination of the serological unit, necessary) it may be possible to obtain a new method for the titration of pharmaceutical prep. of hyaluronidase.

Title : How the Results of Serological Studies on Brucellosis in Large Cattle Should be Interpreted.

Orig Pub : Med. weteryn., 1957, 10, No 1, 6-9

Abstract : It was found that in brucellosis of large cattle, the relationship of positive RA to positive BSR (Blood Serum Reaction) is equal to 1:1 (2700 heads were studied.) In serological studies of 17,000 heads of cattle which were vaccinated with strain V-19, it was noted that after several days to 8-10 months after inoculation both reactions give positive results, later, only RA remains positive, and the relationship RA+/BSR+ equals 155:1. These results are confirmed by serological studies by experimentally inoculating household cattle, free from brucellosis for several years, with live vaccine V-19. BSR is retained, in the author's opinion,

until that time, while in the organism the multiplication of bacteria proceeds (stimulant of brucellosis or live vaccine). With their disappearance, BSR becomes negative. Therefore, in a healthy farm attendant, RA is observed in 50 percent, and BSR only in exceptional cases. -- S.Ya. Faygina

Warsaw, Polski Tygodnik Lekarski, Vol 18, No 18, 29 Apr 63, pp 614-619.

Abstract: [Author's English summary] Author reports control examination of 223 patients with relapses after surgical treatment of varices of the lower limbs. The study was made to establish the reasons for the ineffective operations. Corrective operations were performed in 51 of the cases, and the corrective operation frequently revealed the cause of the relapse. The author enumerates the most frequently observed diagnostic and therapeutic errors, and describes some of the cases. There are 13 references, of which four (4) are Polish, one (1) is Russian, and the others Western.

Production of raw, gray iron for () from Hungarian raw materials with a simultaneous production of an aluminate slag. László Wisnyovskiy, Budapest, Hungary. Report No. 98-115, 125-134-14-15. A small blast furnace was built at Debrecen with a bed of 48.3 cm. Basic cokes from Gánt with SiO_2 4.3-12.0% (mean 4.25%), and Fe 3.9, Mn 2.2, P 0.4, and S 0.02%. The viscosity of the obtained slag seemed to be independent of the ratio $\text{SiO}_2/\text{Al}_2\text{O}_3$ in the presence of the necessary basify, provided the aluminate slag contained 10-20% SiO_2 . The desulfurizing effect of the aluminate slag proved to be definitely stronger than that of silicate slag, thus the S content of gray iron ranged below 0.01%. The reduction of Si needed more coke than in the case of silicate slag. About 90 cm kg. coke can be spared if () kg. ignited lime is applied in place of () kg. limestone, the availability of this method depending on the ratio of the price of coke to lime. The furnace was blasted with air at 56-60°. The following percentages of gases were obtained when limestone and limited lime were used, resp.: CO_2 3.5-4.4; CO 3.8-4.4; CO_2 59.0-72.0; H_2 33.0; H_2 1.8-2.4; CH_4 0.1-0.5; O_2 0.4-0.5. The obtained gray iron showed very fine porosity structure and contained Al 0.02-0.4%. It was, however, inclined to overcooling. The obtained aluminate slag showed very good hydraulic properties after a simple grinding. The concrete made of a good, aluminate slag with 10% SiO_2 had after 28 days pressing strength values of 6-700 and 6-950 kg./sq. cm. Aluminate slags with 18-15% SiO_2 were inferior. The alum earth content of the slag can be recovered in a yield of 90-100% by the method of Polsterer.

 Roasting of Mixtures Containing Large Quantities **
 ORIG. PUB. : Przem. chem., 1958, 37, No 12, 789-793

ABSTRACT : In the roasting of anhydrite in rotary kilns for
 the simultaneous production of sulfuric acid and
 portland cement clinker, a pronounced appearance
 of the liquid phase has been noticed. This liquid
 phase causes sticking of clinker particles which
 form rings on the kiln lining. The authors at-
 tribute such a phenomenon to the presence of ex-
 cessive quantities of the undecomposed CaSO_4 in
 *Concrete.

ABSTRACT : the kiln, which acts as a flux and facilitates
Con'd fusion of the material in the zones of high temperature. A method for the determination of clinker's sticking temperature was developed and checked under laboratory condition. It is based on the subjection of two samples of a mixture made of anhydrite, clay and coke (one laying on top of the other) to a rapid heating in a furnace up to a prescribed temperature, followed by cooling. By gradually increasing temperature, a temperature level is reached at which a mild fusion or sticking of the clinker grains takes place, and,

ABSTRACT : hence, the two samples bind together. It was
Con'd established that sticking temperature of the mixture increases with the degree of CaSO_4 decomposition as the mixture is passed through the furnace. For a well roasted clinker it exceeds 1450° . It was confirmed, that a raw mixture, containing increased quantity of CaSO_4 , begins to stick at relatively low temperatures ($<1200^\circ$) as it passes through a fusion zone. Therefore, it is of considerable importance to accelerate the decomposition of CaSO_4 as it passes through low temperature

AUTHOR: Wiszniewski, Wacław

TITLE: Some Remarks Pertaining to the Meteorological Network in Poland
(Marginal Remarks Related to the Work on the Polish Climatic Atlas)

PERIODICAL: Przegląd Geofizyczny (d. Przegląd Meteorologiczny i Hydrologiczny),
1960, No. 1, pp 3 - 18

TEXT: This article is the first paper of a series of studies carried out in the PIHM (State Institute for Hydrology and Meteorology) for the purpose of improving the distribution of meteorological stations. Its aim is to present the actual state of the meteorological network in Poland. Before approaching the main subject of his paper the author makes some remarks of a general nature. In his opinion the state of meteorological studies and investigations all over the world is not satisfactory. The proof of this - among others - is the conclusion reached by the Meteorological Committee of the US Academy of Sciences, which found that the meteorological studies had been neglected in the States and recommended an increased financial aid and the establishment of a National Institute for Meteorological Research. The author thinks that the ground meteorological stations and the

Card 1/4

P/027/60/000/01/01/013

Some Remarks Pertaining to the Meteorological Network in Poland (Marginal Remarks
Related to the Work on the Polish Climatic Atlas)

aerological stations should be evenly distributed on the entire surface of the earth. It is possible for general meteorological and climatological purposes to define the number of meteorological stations which should cover certain areas or to define the density of meteorological stations doing a particular type of observation in a given area. If we assume that the distance from one meteorological station to another should be 100 km, the range of one meteorological station would cover 7,850 km². To cover the entire land surface of the earth we should have 18,974 meteorological stations. According to the official publication of the OMM (World Meteorological Organization) there were on February 1, 1959, 2,701 synoptic stations making 1 to 7 observations during 24 hours (Table 1). The number of synoptic stations in the VI (Europe) Region was 1,442 and 954 respectively. In Poland there are 64 synoptic stations of the first type and 4 stations of the second type (Table 2 and 3). In addition to that there are 400 climatological stations, 2,042 precipitation stations and a certain number of stations and observation posts, which deal with some particular meteorological phenomena (Table 3). There is also a number of various hydrological stations and observation posts (Table 4). Ac-

Card 2/4

P/027/60/000/01/01/013

Some Remarks Pertaining to the Meteorological Network in Poland (Marginal Remarks Related to the Work on the Polish Climatic Atlas)

According to Professor E. Romer [Ref. 5] the Polish meteorological network is not only to scarce in some places but it is also unscientifically distributed. This opinion is confirmed by the examination of the map of distribution of synoptic stations in Poland. The map was drawn by S. Jarosz [Ref. 3] and based on works of Galon Klimaszewski, Kondracki and Pietkiewicz as well as Czubiński, Mroczkiewicz and Szafer. Although 40 stations should be sufficient to cover the entire territory of Poland, it can be seen from the map that 68 stations leave some places not quite covered owing to bad distribution. As far as the climatological stations are concerned the author assumes that one station should cover an area with a radius of 50 km, i.e. an area of $1,962.5 \text{ km}^2$, then the entire Poland territory would be completely covered by 159 stations. If, however, one station covers $1,000.48 \text{ km}^2$ 312 stations would be required. From the examination of the map it appears again that the present 400 stations do not cover the entire territory. Owing to bad distribution, there are too many in some areas and not enough in others. The author suggests that geographic and hydrographic regions should form the foundation for a proper distribution of the meteorological network in Poland. All 79 geographical regions (according to Professor E. Romer there are 53 regions and according

Card 3/4

P/027/60/000/01/01/013

Some Remarks Pertaining to the Meteorological Network in Poland (Marginal Remarks
Related to the Work on the Polish Climatic Atlas)

to R. Guminski only 21) should have a network of observation points of approximately equal density. This applies also to observation of precipitation in the 34 hydro-graphic regions. The detailed list of the geographical regions is contained in the article. The special networks such as pluviographic, evaporometric, actinometric etc., should be arranged in such a way that at least one observation point be established in every region. The observation points should be placed in the most representative part of the region. There are four maps, one graph, six tables and eight references, 6 of which are Polish, one American and one French.

TITLE: Some Remarks Concerning Meteorological Seasons of the Year in Poland
From the Point of View of the Normal Temperature

PERIODICAL: Przegląd Geofizyczny (d.Przegląd Meteorologiczny i Hydrologiczny),
1960, No. 1, pp 31 - 39

TEXT: In this article the author tries to determine the number of the yearly meteorological seasons in Poland through an analysis of the yearly course of temperature changes. In his opinion the problem of meteorological seasons has not yet been completely solved. This concerns especially the areas in the temperature zone with a transitory climate between Maritime and Continental. The Polish climate belongs to this type. One of its characteristics is the great wealth of atmospheric conditions. It is particularly changeable during the critical seasons. In our latitudes the course of temperature of the air well illustrates the seasons of the year. The author analyses the yearly course of temperature of given parts and of the entire territory of Poland (Figure 1). As the present Polish territory has almost a quadrilateral shape it can be easily divided along a central meridian and a parallel.

Card 1/3

P/027/60/000/01/03/013

Some Remarks Concerning Meteorological Seasons of the Year in Poland From the Point of View of the Normal Temperature

Mean monthly and yearly temperatures taken from a sufficiently long period of observation (1881-1930) [Ref. 8] were taken as a basis of the analysis (Tables I, A and B). Out of the total of 151 stations only 113 were taken into account; the remaining, being located over 350 m above sea level, were disregarded. The mean temperatures for given parts of Poland show considerable differences especially between the western and the eastern parts. From the study of the arrangement of temperature values in 5-grade sections for the consecutive months, the author found five basic groupings. Two border groups with 3 months in each (XII, I, II, and VI, VII, VIII) and three groups with 2 months in each (III and XI, IV and X, V and IX) (Figure 3). From this he drew the conclusion that there are 8 meteorological seasons in Poland. He confirmed this conclusion by the analysis of Table II and III. The Table II shows the average dates of transitions of threshold temperatures for given areas during the entire year. And Table III, resulting from Table II, shows the number of days each particular season lasts. It can be seen that the summer in Poland lasts 83 days and winter 82 days. The duration of other seasons fluctuates between 28 and 37 days. If instead of the entire Polish territory,

Card 2/3

P/027/60/000/01/03/013

Some Remarks Concerning Meteorological Seasons of the Year in Poland From the Point of View of the Normal Temperature

particular areas are taken into consideration, the duration of the seasons is different for different areas e.g. winter in the NE area lasts 99 days and in the SW area 69 days. The author distinguishes the following seasons: winter (cold), early spring (cool), spring (temperate), early summer (temperate), summer (warm), late summer (temperate), fall (temperate), early winter (cool) (Table III). This distinction to his opinion is also correct from the phenological point of view. There are 3 tables, 3 figures and 8 references, 7 of which are Polish and one West German. This article is also published in English in the quarterly Acta Geophysica Polonica (1959, No. 3 - 4).
